## 第二章: Haskell编程第一步

### GHC, Prelude, Scripts

Adapted from Graham's Lecture Slides.

# **Glasgow Haskell Compiler**

- GHC is the leading implementation of Haskell, and comprises a compiler and interpreter;
- The interactive nature of the interpreter makes it well suited for teaching and prototyping;
- GHC is freely available from:

www.haskell.org/platform

The interpreter can be started from the terminal command prompt \$ by simply typing <u>ghci</u>:

\$ ghci
GHCi, version 8.8.4: https://www.haskell.org/ghc/ :? for help
Prelude>

The GHCi prompt > means that the interpreter is now ready to evaluate an expression.

For example, it can be used as a desktop calculator to evaluate simple numeric expresions:

> 2+3*4
14
> (2+3)*4
20
> sart $(3^2 + 4^2)$
5.0

### **The Standard Prelude**

Haskell comes with a large number of standard library functions. In addition to the familiar numeric functions such as + and \*, the library also provides many useful functions on <u>lists</u>.

Select the first element of a list:

Remove the first element from a list:

Select the nth element of a list:

Select the first n elements of a list:

Remove the first n elements from a list:

Calculate the length of a list:

Calculate the sum of a list of numbers:

Calculate the product of a list of numbers:

Append two lists:

Reverse a list:

> reverse [1,2,3,4,5]
[5,4,3,2,1]

### **Function Application**

In <u>mathematics</u>, function application is denoted using parentheses, and multiplication is often denoted using juxtaposition or space.

# In <u>Haskell</u>, function application is denoted using space, and multiplication is denoted using \*.

Moreover, function application is assumed to have <u>higher priority</u> than all other operators.

<u>Mathematics</u>	Haskell
f(x)	fx
f(x,y)	fxy
f(g(x))	f (g x)
f(x,g(y))	f x (g y)
f(x)g(y)	f x * g y

## **Haskell Scripts**

- As well as the functions in the standard library, you can also define your own functions;
- New functions are defined within a <u>script</u>, a text file comprising a sequence of definitions;
- By convention, Haskell scripts usually have a <u>.hs</u> suffix on their filename. This is not mandatory, but is useful for identification purposes.

When developing a Haskell script, it is useful to keep two windows open, one running an editor for the script, and the other running GHCi.

Start an editor, type in the following two function definitions, and save the script as <u>test.hs</u>:

```
double x = x + x
quadruple x = double (double x)
```

Leaving the editor open, in another window start up GHCi with the new script:

\$ ghci test.hs

Now both the standard library and the file test.hs are loaded, and functions from both can be used:

# Leaving GHCi open, return to the editor, add the following two definitions, and resave:

<pre>factorial n = product [1n]</pre>									
average	ns	=	sum	ns	`div`	length	ns		

#### Note:

- div is enclosed in <u>back</u> quotes, not forward;
- x `f` y is just <u>syntactic sugar</u> for f x y.

GHCi does not automatically detect that the script has been changed, so a <u>reload</u> command must be executed before the new definitions can be used:

```
> :reload
Reading file "test.hs"
> factorial 10
3628800
> average [1,2,3,4,5]
3
```

## **Useful GHCi Commands**

### <u>Command</u> <u>Meaning</u>

:load *name* load script *name* :reload reload current script :set editor *name* set editor to *name* :edit *name* edit script *name* :edit edit current script :type *expr* show type of *expr* show all commands :? quit GHCi :quit

## **Naming Requirements**

• Function and argument names must begin with a lower-case letter. For example:

By convention, list arguments usually have an <u>s</u> suffix on their name. For example:

#### **The Layout Rule**

In a sequence of definitions, each definition must begin in precisely the same column:

The layout rule avoids the need for explicit syntax to indicate the grouping of definitions.

作业

- **2-1** Try out slides 3-8 and 14-17 using GHCi.
- 2-2 Fix the syntax errors in the program below, and test your solution using GHCi.

2-3 Show how the library function <u>last</u> that selects the last element of a list can be defined using the functions introduced in this lecture.

2-4 Can you think of another possible definition?

2-5 Similarly, show how the library function <u>init</u> that removes the last element from a list can be defined in two different ways.
