第4章：函数的定义

Function Definition

**主要知识点：利用已有函数定义新函数、
条件表达式、模式匹配、Lambda表达式、Section**

利用已有函数定义新函数

问题1 判断一个整数是不是偶数

```
even :: Int -> Bool  
even n = mod n 2 == 0
```

问题2 求一个浮点数的倒数

```
recip :: Double -> Double  
recip x = 1 / x
```

问题2 将一个序列在位置n分开

```
splitAt :: Int -> [a] -> ([a], [a])  
splitAt n xs = (take n xs, drop n xs)
```

Conditional Expressions

As in most programming languages,
functions can be defined using **conditional expressions**.

```
abs :: Int -> Int  
abs n = if n >= 0 then n else -n
```

abs takes an integer **n** and returns **n** if it is non-negative and **-n** otherwise.

Conditional Expressions

Conditional expressions can be nested

```
signum :: Int -> Int
signum n = if n < 0 then -1 else
           if n == 0 then 0  else 1
```

- * In Haskell, conditional expressions must always have an **else** branch, which avoids any possible ambiguity problems with nested conditionals.

Guarded Equations

As an alternative to conditionals, functions can also be defined using **guarded equations**.

```
abs :: Int -> Int
abs n | n >= 0 = n
      | otherwise = -n
```

Guarded Equations

- ♣ Guarded equations can be used to make definitions involving multiple conditions easier to read .

```
signum :: Int -> Int
signum n | n < 0    = -1
         | n == 0   =  0
         | otherwise = -1
```

* The catch all condition `otherwise` is defined in `Prelude` by `otherwise = True`

Pattern Matching

Many functions have a particularly clear definition using pattern matching on their arguments.

```
not :: Bool -> Bool
not False = True
not True  = False
```

not maps **False** to **True**, and **True** to **False**

- ✿ Functions can often be defined in many different ways using pattern matching. For example:

```
(&&) :: Bool -> Bool -> Bool
True  && True   = True
True  && False  = False
False && True   = False
False && False  = False
```

can be defined more compactly by

```
(&&) :: Bool -> Bool -> Bool
True  && True   = True
_     && _     = False
```

- ✿ However, the following definition is more efficient, because it avoids evaluating the second argument if the first argument is **False**

```
(&&) :: Bool -> Bool -> Bool
True  && b = b
False && _ = False
```

- * The underscore `_` is a **wildcard** pattern that matches any argument value.

- ✦ Patterns are matched *in order*.
- ✦ For example, the following definition always returns False:

```
(&&) :: Bool -> Bool -> Bool
_    && _    = False
True && True = True
```

- ✦ Patterns may not repeat variables.
- ✦ For example, the following definition gives an error:

```
(&&) :: Bool -> Bool -> Bool
b    && b    = b
_    && _    = False
```

List Patterns

Internally, every non-empty list is constructed by repeated use of an operator (`:`) called “cons” that adds an element to the start of a list.

```
[1, 2, 3, 4]
```

```
==
```

```
1:(2:(3:(4:[])))
```

List Patterns

Functions on lists can be defined using **x:xs** patterns

```
head :: [a] -> a
head (x:_) = x
```

- ▶ **head** map any non-empty list to its first element.

```
tail :: [a] -> [a]
tail (_:xs) = xs
```

- ▶ **tail** map any non-empty list to its tail list.

List Patterns

- ✿ `x:xs` patterns only match non-empty lists.

```
program — ghc-9.4.2 -B/Users/nrutas/.ghcup/ghc/9.4.2/li...
ghci>
ghci> head [1,2,3]
1
ghci>
ghci> head []
*** Exception: Prelude.head: empty list
```

- ✿ `x:xs` patterns must be parenthesised, because application has priority over `(:)`.
- ✿ For example, the following definition gives an error:

```
head x:_ = x
```

Tuple Patterns

```
-- Extract the first component of a pair.
```

```
fst :: (a,b) -> a
```

```
fst (x,_) = x
```

```
-- Extract the second component of a pair.
```

```
snd :: (a,b) -> b
```

```
snd (_,y) = y
```

Lambda Expressions

Functions can be constructed without naming the functions by using **lambda expressions**.

$\lambda x \rightarrow x + x$

- the nameless function that takes a value x and returns the result $x + x$

Why Lambda Expressions

- ✿ Lambda expressions can be used to give a formal meaning to functions defined using currying.

```
add x y = x + y
```

||

```
add = \x -> (\y -> x + y)
```

Why Lambda Expressions

- ✿ Lambda expressions can be used to avoid naming functions that are only referenced once.

```
odds n = map f [0..n-1]
  where
    f x = x * 2 + 1
```

```
-- defined in Prelude
map :: (a -> b) -> [a] -> [b]
map _ [] = []
map f (x:xs) = f x : map f xs
```

can be simplified to

```
odds n = map (\x -> x * 2 + 1) [0..n-1]
```

Operator Sections

An operator written between its two arguments can be converted into a curried function written before its two arguments by using parentheses.

```
nrutas — ghc-9.4.2 -B/Users/nrut...
ghci>
ghci> 1 + 2
3
ghci> (+) 1 2
3
ghci> :type (+)
(+) :: Num a => a -> a -> a
[ghci>
```

Operator Sections

- ✿ This convention also allows one of the arguments of the operator to be included in the parentheses.

```
nrutas — ghc-9.4.2 -B/Users/...
ghci>
ghci> (+1) 2
3
ghci> :type (+1)
(+1) :: Num a => a -> a
ghci>
ghci> (1+) 2
3
ghci> :type (1+)
(1+) :: Num a => a -> a
ghci>
ghci> (1-) 2
-1
ghci> :type (1-)
(1-) :: Num a => a -> a
ghci>
```

```
nrutas — ghc-9.4.2 -B/Users/nruta...
ghci>
ghci> :type (1-)
(1-) :: Num a => a -> a
ghci>
ghci> :type (-1)
(-1) :: Num a => a
ghci> (-1) 2
<interactive>:25:1: error:
```

Operator Sections

In general, if \oplus is an operator then functions of the form (\oplus) , $(x \oplus)$ and $(\oplus y)$ are called **sections**.

$$(\oplus) = \backslash x \rightarrow (\backslash y \rightarrow x \oplus y)$$

$$(x \oplus) = \backslash y \rightarrow x \oplus y$$

$$(\oplus y) = \backslash x \rightarrow x \oplus y$$

Why Operator Sections

- ✿ Useful functions can sometimes be constructed in a simple way using sections.

$(+ 1)$	successor function
$(1 /)$	reciprocation function
$(* 2)$	doubling function
$(/ 2)$	halving function

作业

作业

4-1 Consider a function `safetail` that behaves in the same way as `tail`, except that `safetail` maps the empty list to the empty list, whereas `tail` gives an error in this case.

Define `safetail` using:

- (a) a conditional expression;
- (b) guarded equations;
- (c) pattern matching.

*Hint: the library function `null :: [a] -> Bool` can be used to test if a list is empty.

作业

- 4-2 The **Luhn** algorithm is used to check bank card numbers for simple errors such as mistyping a digit, and proceeds as follows:
- (1) consider each digit as a separate number;
 - (2) moving left, double every other number from the second last; (从右向左, 偶数位的数字乘2)
 - (3) subtract 9 from each number that is now greater than 9; add all the resulting numbers together;
 - (4) if the total is divisible by 10, the card number is valid.

Define a function **luhn** :: **Int** -> **Int** -> **Int** -> **Int** -> **Bool** that decides if a four-digit bank card number is valid. For example:

```
> luhn 1 7 8 4  
True
```

```
> luhn 4 7 8 3  
False”
```

第4章：函数的定义

Function Definition

就到这里吧
