

第 06 章: List Comprehension

主要知识点:

○ Generator / Guard / String Comprehension

◇ List Comprehension

In mathematics, the **set comprehension** notation can be used to *construct new sets from old sets*.

$$\{ x^2 \mid x \in \{1,2,3,4,5\} \}$$

In Haskell, a similar **list comprehension** notation can be used to *construct new lists from old lists*.

$$[x^2 \mid x \leftarrow [1..5]] \quad === \quad [1, 4, 9, 16, 25]$$

◇ Generator

The expression `x <- [1..5]` is called a **generator**, as it states how to generate values for x.

Comprehensions can have *multiple* generators, separated by commas. For example:

$$\begin{aligned} & [(x,y) \mid x \leftarrow [1, 2, 3], y \leftarrow [4, 5]] \\ === & [(1,4), (1,5), (2,4), (2,5), (3,4), (3,5)] \end{aligned}$$

Changing the order of the generators changes the order of the elements in the final list:

$$\begin{aligned} & [(x,y) \mid y \leftarrow [4, 5], x \leftarrow [1, 2, 3]] \\ === & [(1,4), (2,4), (3,4), (1,5), (2,5), (3,5)] \end{aligned}$$

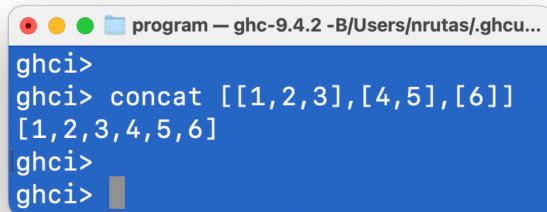

Dependant Generator: Later generators can depend on the variables that are introduced by earlier generators.

$$[(x,y) \mid x \leftarrow [1..3], y \leftarrow [x..3]]$$

```
=== [ (1,1), (1,2), (1,3), (2,2), (2,3), (3,3) ]
```

Example: Using a dependant generator we can define the library function that *concatenates* a list of lists:

```
concat :: [[a]] -> [a]
concat xss = [ x | xs <- xss, x <- xs ]
```

```
program — ghc-9.4.2 -B/Users/nrutas/ghcu...
ghci>
ghci> concat [[1,2,3],[4,5],[6]]
[1,2,3,4,5,6]
ghci>
ghci>
```

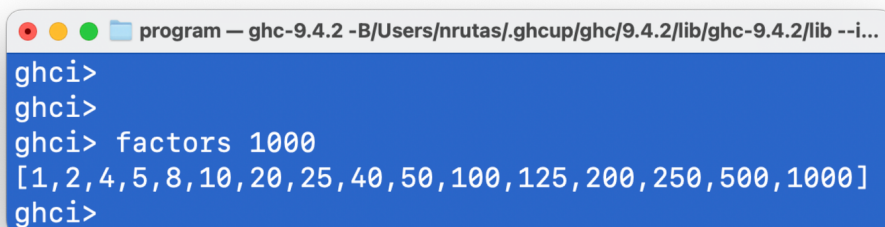

✧ Guards

List comprehensions can use **guards** to restrict the values produced by earlier generators.

```
[ x | x <- [1..10], even x ]
=== [ 2, 4, 6, 8, 10 ]
```

Example: Using a guard we can define a function that maps a positive integer to its list of factors:

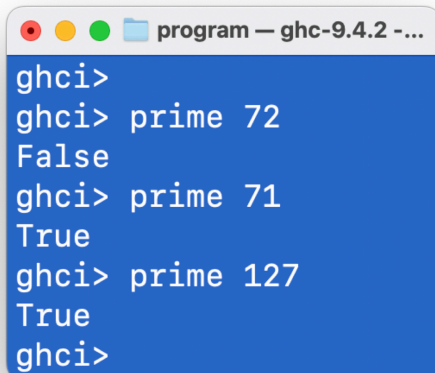

```
factors :: Int -> [Int]
factors n = [ x | x <- [1..n], mod n x == 0 ]
```

```
program — ghc-9.4.2 -B/Users/nrutas/ghcup/ghc/9.4.2/lib/ghc-9.4.2/lib --i...
ghci>
ghci>
ghci> factors 1000
[1,2,4,5,8,10,20,25,40,50,100,125,200,250,500,1000]
ghci>
```

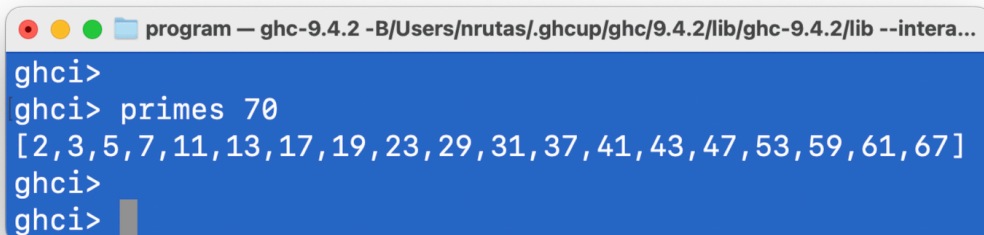

Example: A positive integer is prime if its only factors are 1 and itself. Hence, using factors we can define a function that decides if a number is prime:

```
prime :: Int -> Bool
prime n = factors n == [1,n]
```

```
ghci>
ghci> prime 72
False
ghci> prime 71
True
ghci> prime 127
True
ghci>
```

```
primes :: Int -> [Int]
primes n = [x | x <- [2..n], prime x]
```

```
ghci>
ghci> primes 70
[2,3,5,7,11,13,17,19,23,29,31,37,41,43,47,53,59,61,67]
ghci>
ghci>
```

✧ The **Zip** Function

A useful library function is `zip`, which maps two lists to a list of pairs of their corresponding elements.

```
zip :: [a] -> [b] -> [(a,b)]
zip [] _ = []
zip _ [] = []
zip (a:as) (b:bs) = (a,b) : zip as bs
```

```
program — ghc-9.4.2 -B/Users/nrutas/.ghcup/ghc/9.4....
ghci>
ghci>
ghci> zip ['a','b','c'] [1,2,3,4]
[('a',1),('b',2),('c',3)]
ghci>
```

Example: Using `zip`, we can define a function that returns the list of all pairs of adjacent elements from a list:

```
pairs :: [a] -> [(a,a)]
pairs xs = zip xs (tail xs)
```

```
program — ghc-9.4.2 -B/Users/nrutas/.ghcup/ghc/9.4.2/lib/ghc-9.4.2/lib --interactive...
ghci>
ghci>
ghci> pairs [1..10]
[(1,2),(2,3),(3,4),(4,5),(5,6),(6,7),(7,8),(8,9),(9,10)]
ghci>
```

Example: Using `zip`, we can define a function that decides if the elements in a list are sorted:

```
sorted :: Ord a => [a] -> Bool
sorted xs = and [x <= y | (x,y) <- pairs xs]
```

```
program — ghc-9.4.2 -B...
ghci>
ghci> sorted [1..10]
True
ghci> sorted [1,3,2,4]
False
ghci>
```

Example: Using `zip`, we can define a function that returns the list of all positions of a value in a list:

```
positions :: Eq a => a -> [a] -> [Int]
positions x xs = [ i | (x',i) <- zip xs [0..], x == x' ]
```

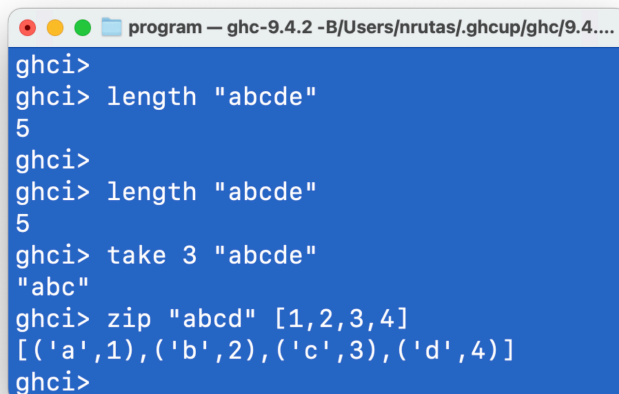

```
program — ghc-9.4.2 -B/Users/nrutas/.ghcup/ghc/9.4.2...
ghci>
ghci>
ghci> positions 0 [1,0,0,1,0,1,1,0]
[1,2,4,7]
ghci>
```

✧ String Comprehension

A **string literal** is a sequence of characters enclosed in double quotes.

```
"abcd" :: String
=== ['a', 'b', 'c', 'd'] :: [Char]
```

Because strings are just special kinds of lists, any polymorphic function that operates on lists can also be applied to strings.

```
program — ghc-9.4.2 -B/Users/nrutas/.ghcup/ghc/9.4.2...
ghci>
ghci> length "abcde"
5
ghci>
ghci> length "abcde"
5
ghci> take 3 "abcde"
"abc"
ghci> zip "abcd" [1,2,3,4]
[('a',1),('b',2),('c',3),('d',4)]
ghci>
```

Similarly, list comprehensions can also be used to define functions on strings, such counting how many times a character occurs in a string.

```
count :: Char -> String -> Int
count x xs = length [ x' | x' <- xs, x == x' ]
```

```
program — ghc-9.4.2 -B/Users/nrutas/gh...
ghci>
ghci>
ghci> count 'g' "yanglegeyang"
3
ghci>
```

✧ 凯撒加密问题

To encode a string, Caesar simply replaced each letter in the string by the letter three places further down in the alphabet, wrapping around at the end of the alphabet.

```
program — ghc-9.4.2 -B/Users/nrutas/ghcup/g...
ghci>
ghci> :type encode
encode :: Int -> String -> String
ghci>
ghci> encode 3 "haskell is fun"
"kdvnhoo lv ixq"
ghci>
ghci> encode (-3) "kdvnhoo lv ixq"
"haskell is fun"
ghci>
ghci> :type crack
crack :: String -> String
ghci>
ghci> crack "kdvnhoo lv ixq"
"haskell is fun"
ghci>
```

加密 / encode

```
import Data.Char(ord, chr, isLower)
-- ord :: Char -> Int           // 将字符转换为编码值
-- chr :: Int -> Char          // 将编码值转换为字符
-- isLower :: Char -> Bool    // 判断字符是否为小写字母

encode :: Int -> String -> String
encode n xs = [ shift n x | x <- xs ]
```

```

shift :: Int -> Char -> Char
shift n c | isLower c = int2let $ mod (let2int c + n) 26
          | otherwise = c

let2int :: Char -> Int
let2int c = ord c - ord 'a'

int2let :: Int -> Char
int2let n = chr $ ord 'a' + n

```

解密 / crack

The key to cracking the Caesar cipher is the observation that some letters are used more frequently than others in English text.

```

table :: [Float]
table = [ 8.1, 1.5, 2.8, 4.2, 12.7, 2.2, 2.0, 6.1, 7.0,
         0.2, 0.8, 4.0, 2.4, 6.7, 7.5, 1.9, 0.1, 6.0,
         6.3, 9.0, 2.8, 1.0, 2.4, 0.2, 2.0, 0.1 ]
-- table 中存放了 a,b,...,d 26 个英文字母在英文中出现的概率/频率

```

A standard method for comparing a list of observed frequencies *os* with a list of expected frequencies *es* is the *chi-square statistic*, defined by the following summation in which

- n denotes the length of the two lists, and
- xs_i denotes the i th element of a list xs counting from zero:

```

crack :: String -> String
crack xs = encode (-factor) xs
  where
    factor = position (minimum chitab) chitab
    -- minimum: a function exported by Prelude

    -- 计算每种加密偏移量下的 chisqr
    chitab = [ chisqr (rotate n table') table | n <- [0..25] ]

```

```
-- 计算密文中字母的出现频率
table' = freqs xs

freqs :: String -> [Float]

chisqr :: [Float] -> [Float] -> Float
```

作业 01

请给出凯撒解密函数的完整定义:

```
crack :: String -> String
```

(仅考虑“明文中仅包含小写字母和空格”的情况)

作业 02

A triple (x,y,z) of positive integers is called pythagorean,
if $x^2 + y^2 = z^2$.

Using a list comprehension, define a function

```
pyths :: Int -> [(Int,Int,Int)]
```

that maps an integer n to all such triples with components in $[1..n]$.

For example:

```
ghci> pyths 5
[ (3,4,5), (4,3,5) ]
```

作业 03

A positive integer is perfect if it equals the sum of all of its factors, excluding the number itself.

Using a list comprehension, define a function

```
perfects :: Int -> [Int]
```

that returns the list of all perfect numbers up to a given limit.

For example:

```
ghci> perfects 500  
[ 6, 28, 496 ]
```

作业 04

The scalar product of two lists of integers xs and ys of length n is give by the sum of the products of the corresponding integers:

Using a list comprehension, define a function that returns the scalar product of two lists.
